FOREWORD

This document summarizes the results of data and data analysis of two wind tunnel test programs to define the plume induced environments on the Space Shuttle vehicle. The work was performed for the NASA Marshall Space Flight Center, Huntsville, Alabama. The NASA technical monitors for this study was Mssrs. Kenneth L. Blackwell and Joseph L. Simms of the Systems Dynamics Laboratory.

C_{P_i}	Pressure coefficient for model surface tap i.
ΔC_{P_i}	$C_{P_{\text{Power On}}} - C_{P_{\text{Power Off}}}$
P_{c_j}	Chamber pressure (absolute) for nozzle j, psia
P_{e_j}	Exit pressure (absolute) for nozzle j. psia
CPR_j	Chamber-pressure ratio for nozzle j
γ_j	Ratio of specific heats for nozzle J
$P_c/P_{\infty \text{ ORB}}$	SSME chamber to freestream pressure ratio
$P_c/P_{\infty \text{ SRB}}$	SRB chamber to freestream pressure ratio
P_c/P_e	Chamber to exit nozzle pressure ratio
P_c/P_{wall}	Chamber to nozzle wall pressure ratio
M_j	Plume boundary Mach number at nozzle lip
M_E	Nozzle exit Mach number at nozzle wall (inviscid)
N	Exponent of ratio of specific heats and in similarity parameters
δ_j	Initial plume expansion angle
<u>Deflections:</u>	
δ_{E_I}	Left inboard elevon setting, corrected for load deflection, deg.
δ_{E_O}	Left outboard elevon setting, corrected for load deflection, deg.
γ_{NJ}	Pitch-angle of nozzle-j axis in a plane parallel to the Orbiter plane-of-symmetry, deg.
γ_{N_j}	Pitch-angle of nozzle-j axis in a plane which yaws with the nozzle, deg.
ψ_{N_j}	Yaw-angle of nozzle-j axis in an Orbiter waterplane, deg.

Test Operations:

M	Freestream Mach number.
Re/ft	Freestream unit Reynolds number, ft ⁻¹ .
q	Freestream dynamic pressure, psf.
P _∞	Freestream static pressure, psia.
P _T	Freestream total pressure, psia.
T	Freestream static temperature, °R.
T _T	Freestream total temperature, °R.
α	Model angle-of-attack, deg.
β	Model angle-of-sideslip, deg.
T _T SRB	SRB supply total temperature, °R.
T _T MPS	MPS supply total temperature, °R.
P _C MPS	MPS supply total pressure, psia.
P _C SRB	SRB supply total pressure, psia.

Section I

INTRODUCTION

An analysis of pressure and strain-gage data from Space Shuttle wind tunnel test IA119 and IA138 was performed to define the influence on aerodynamic characteristics resulting from the main propulsion system (MPS) and solid rocket booster (SRB) plumes. Aerodynamic characteristics of each of the elements, the components and total vehicle of the Space Shuttle vehicle during ascent flight was to be considered.

Test IA119 was a transonic wind tunnel test of a 0.02 scale model of the Space Shuttle launch vehicle. The test was conducted in the 11 x 11-foot section of the NASA/AMES Research Center Unitary Plan Wind Tunnel. Pressure data were obtained over the aft portions of the space shuttle wind tunnel model in addition to wing and elevon gage data.

Test IA138 was a supersonic wind tunnel test of a 0.01-scale model of the Space Shuttle launch vehicle. The test was conducted in the 9 x 7-foot section of the NASA/AMES Research Center Unitary Plan Wind Tunnel. Pressure data were obtained over the aft portions of the space shuttle wind tunnel model. Wing and elevon gage data were also obtained.

The simulant gas used to develop the model exhaust plumes was air. A portion of the tests were devoted to testing at various power levels. Data from the power level portion was used in conjunction with prototype possibility curves to evaluate nominal power levels. The nominal power levels were used during the investigation of changes in model attitude, elevon deflections and nozzle gimbal angles on the aerodynamic characteristics. The simulation parameter used to develop nominal power levels was $[\delta_j \gamma_j^N]_{\text{PROT}} = [\delta_j \gamma_j^N]_{\text{MODEL}}$ where N varies with Mach number.

Aerodynamic loads induced by the plumes were developed for the Space Shuttle base areas and forebody areas. The base areas are, the orbiter base including nozzles, the ET base and the SRB base. The forebody includes those areas of the orbiter forward of the base. The forebody includes the body flap, the wings and elevons, and the ET and SRB areas forward of the base.

A math model of the plume induced aerodynamic characteristics designed to match the forebody aerodynamic math model was developed for a range of Mach numbers. The aerodynamic characteristics of the base are presented in terms of forces and moments versus attitude. The aerodynamic characteristics of the total vehicle base and forebody are presented in terms of aerodynamic coefficients for the range of Mach numbers from 0.6 to 2.5. Aerodynamic characteristics of the elements component base and vehicle forebody are presented for Mach numbers from 0.6 to 2.5. Aerodynamic characteristics are presented vs Mach numbers compatible with Mach numbers used in defining forebody aerodynamic characteristics.

Tolerance values were developed for all plume induced aerodynamic characteristics. The tolerance values were developed in terms of a math model and include simulation parameter uncertainties, model instrumentation uncertainties, model configuration uncertainties (including tunnel-model support interference uncertainties and Reynolds number effects).

The results of the above analysis and math model of the IA119 transonic data are presented in detail in reference 1. The result of the base pressure integration computer program, gage data, and plotted data are presented in the appendix to reference 1.

The results of the analysis and math model of the IA138 supersonic data are presented in reference 2. The results of the IA138 base pressure integration computer program, gage data, and plotted data are presented in the appendix to reference 2.

Brief discussions of the wind tunnel test programs, data analysis tasks and analysis procedures are presented in the following sections. Examples of the results and math models of the results are also presented.

Section II

WIND TUNNEL MODELS

The wind tunnel model used for the IA119 test was a .02 scale Space Shuttle Launch Vehicle configuration. The wind tunnel model is designated - 88 OTS Configuration 140C (modified) Jet - Plume Integrated Space Shuttle Vehicle. The wind tunnel model is essentially the same as was used for an earlier Space Shuttle plume test IA19, conducted in 1974. The major difference being that the contoured SSME flow through nozzles were used during the IA119 test and conical SSME nozzles were used during the IA19 test. The orbiter model was the 140C model configuration which generally represents the OV101 orbiter mold lines. The OV102 mold lines have significant differences in the canopy contour, the wing section near the glove-wing fairing, and the elevon contour. Details of the model configuration can be obtained from the pretest report (reference³).

The model was strut mounted as shown in Figure 2-1. Cold air was supplied through the strut to the SSME and SRB nozzles. An air supply strut was mounted between the ET and orbiter to supply air to the simulated SSME nozzles as shown in Figure 2-2. The SSME nozzles were contoured with an exit plane lip angle of 5 degrees. The SRB nozzles were conical with a lip angle of 27.5 degrees.

The left orbiter wing was strain-gage instrumented to obtain wing shear forces, root bending moments and torsion moments. The inboard and outboard elevons on the left wing were separately strain-gage instrumented to obtain hinge moments. The vertical tail was also strain-gage instrumented to obtain shear, bending moments, and torsion moments. The right orbiter wing and elevons were pressure instrumented. All base, nozzle, and portions of each element forebody area were pressure instrumented.

The flow through MPS nozzles and SRB nozzles were capable of being set at various gimbal-angle positions and several gimbal patterns were investigated. The inboard and outboard elevons were also capable of being set at various deflection angles and data were obtained for a series of elevon deflection combinations.

The wind tunnel model used for the IA138 test was a 0.01 scale space shuttle launch vehicle configuration. The wind tunnel model is designated - 75 OTS Configuration 140C (modified) Jet - Plume Integrated Space Shuttle Vehicle. The orbiter model was the 140C model configuration which generally represents the OV101 orbiter mold lines. The OV102 mold lines have significant differences in the canopy contour, the wing section near the glove-wing fairing, and the elevon contour. Details of the model configuration can be obtained from the pretest report (reference 4).

The model was strut mounted similar to the IA119 model as shown in Figure 2-1. Cold air was supplied through the strut to the SSME and SRB nozzles. An air supply strut was mounted between the ET and orbiter to supply air to the simulated SSME nozzles as shown in Figure 2-2. The SSME nozzles were conical with an exit plane lip angle of 11.0 degrees. The SRB nozzles were conical with a lip angle of 27.5 degrees.

A partial right orbiter wing was strain-gage instrumented to obtain wing shear forces, root bending moments and torsion moments. The inboard and outboard elevons on the left wing were also separately strain-gage instrumented to obtain hinge moments. All base, nozzle, and portions of each element forebody were pressure instrumented.

TEST CONDITIONS

The IA119 and the IA138 wind tunnel test program was essentially conducted in two parts. Part one was a power variation test at zero attitude, where chamber pressure of the MPS and SRB model nozzles was varied. Part two was a test program at a nominal power level that included various elevon deflections, nozzle gimbal patterns, and attitudes.

Base pressure data, from the power variation tests (Part 1), was evaluated at the test site along with prototype plume characteristics to evaluate the nominal model nozzle plume characteristics and model chamber pressures. (See Section V for plume simulation discussion). These tests were conducted at zero angle of attack and zero angle of sideslip. Tests were conducted for a series of Mach numbers from 0.6 to 2.5.

Part 2 of the test programs consisted of testing the model using the nominal power levels developed in Parts 1 over a range of attitudes and configurations (elevon deflections, gimbal angles, etc.). Data were obtained at nominal angles of attack of -8, -6, -4, 0, and +4 degrees.—The angles of sideslip were nominally 0, and ± 6 or ± 4 degrees.

Tests were conducted at various elevon deflections corresponding to Schedule 6 and probable variations about schedule 6. Schedule 6 elevon deflections are presented in Figure 3-1. Plots of the various inboard and outboard elevon deflection angles evaluated during the test along with the nominal schedule 6 value are presented in Figures 3-2 through 3-10. The elevon deflection closest to schedule 6 that was used to develop the plume induced aerodynamic data base is shown in each figure.

Section IV

WIND TUNNEL MODEL NOZZLE CALIBRATION ANALYSIS

An analysis of the model nozzle calibration data was performed to determine nozzle flow characteristics for the evaluation of model power levels. A range of model power levels were required for the power level variation portion of the test. Model nozzle wall pressures and exit plane pressures were plotted and compared with MOC results to evaluate the nozzle flow characteristics and to evaluate chamber to exit pressure ratios. The chamber to exit pressure ratios were required to evaluate the model plume characteristics.

Initially it was anticipated that several model nozzle configurations would be used during the IA119 test program and thus a considerable amount of calibration data were evaluated. The IA119 test program ultimately used only the 2% contoured SSME nozzle configuration and the 2% conical SRB nozzle configuration. The nozzle calibration tests were conducted for the IA19 Space Shuttle plume test (reference 5). This test (IA19) used essentially the same model hardware as the IA119 test. The IA138 test program used a 1% conical SSME nozzle configuration and a 1% conical SRB nozzle configuration.

Summary IA119 model nozzle performance data are presented in Figures 4-1 and 4-2 for the SSME model nozzles and the SRB model nozzles respectively. The average chamber to exit plane pressure used for the model SSME nozzle was 49.5. The average chamber to exit plane pressure used for the SRB nozzle was 66.0. These values were used to develop pretest pressure ratios for each Mach number.

Summary IA138 nozzle performance data are presented in Figures 4-3 and 4-4 for the SSME nozzles and the SRB nozzles respectively. The post-test SRB nozzle performance was slightly different from the pre test nozzle performance developed from the nozzle calibration data.

Section V

PLUME SIMULATION

The Space Shuttle plumes were simulated using cold air flowing through model nozzles. The model plume characteristics required to develop base and forebody pressure environments were determined using an iteration procedure requiring the development of "PROTOTYPE POSSIBILITY CURVES". Prototype possibility curves are curves of base pressure or base pressure coefficient versus prototype plume characteristics. An example prototype possibility curve is shown in Figure 5-1. The curve is called possibility curve since it is developed for a range of possible prototype base pressure environments. These curves were developed prior to the wind tunnel test for both the SSME and SRB prototype nozzles. The SSME possibility curves were developed using possible orbiter base pressure coefficients and the SRB possibility curves were developed using SRB possible base pressure environments. During the power level portion of the test, model base pressure data are plotted on the prototype possibility curves as shown in Figure 5-1. The model power level is determined where the model pressure curve crosses the prototype pressure curve. An iteration procedure is used when there are two variables involved that influence the base pressure, i.e. SSME power level and SRB power level. The possibility curves and the model pressure data used to determine the nominal power levels at each Mach number are presented in the Appendix of references 1 and 2.

The form of the plume simulation equation used during the IA119 and IA138 test program was the following (reference 6)

$$\delta_j \gamma_j^N \text{ PROT.} = \delta_j \gamma_j^N \text{ MODEL}$$

where N is a function of Mach number. A plot of N versus Mach number is shown in Figure 5-2 and was obtained from reference 7. This curve was developed by correlating the base pressure in the near field and the far field developed from cold gas air and CF_4 plumes. The plume induced near field and far field areas considered are shown in Figure 5-3. The model configurations used were single body single nozzle, single body triple nozzle and triple body configurations. The triple body configuration was similar to the ET-SRB space shuttle

configuration. The band on the curve represents the range of N for the various models used in the plume technology test (i.e., single body, triple body, etc.). The criteria used for correlation of the plume technology data was that the same base pressure occur for a five percent or less change in similarity parameter. The band represents the total spread of N for the various model and nozzle configurations considered in the plume technology program.

Recent analysis (Reference 8) has identified a new similarity parameter that has the functional form

$$\frac{M_j \delta_j}{f(M_{EX}) g(\gamma_j)}$$

where f , g appear to depend weakly upon M_∞ and configuration.

The functions f and g have been defined for several model configurations and Mach numbers. The form of the various base pressure correlation parameters is presented in Table 5-1. These new similarity parameters, namely

$$\frac{M_j \delta_j}{M_E (.25) \gamma_j}, \quad \frac{M_j \delta_j}{M_E (.25) \gamma_j (.5)}, \quad \text{and} \quad \frac{M_j \delta_j}{\gamma_j}$$

for the IA138 test results along with the value of $\delta_j \gamma_j^N$ (see Section VII).

Section VI

DATA ANALYSIS

Five computer codes were used to analyze the test data. These programs are: 1. SORT program, 2. Power Delta program, 3. Sigma V Punch, 4. Wind Tunnel Pressure Data Analysis and 5. Plume Integration. A brief discussion of each of these programs is presented below.

SORT PROGRAM

The SORT Program was used to sort the run and sequence data sets into basic groups of four. The four run groups consist of $+\beta$ power-on, $+\beta$ power-off, $-\beta$ power-on and $-\beta$ power-off. The four run data sets were arranged in angle of attack sets of -8, -4, 0, 4. Flags were set to note α , β , Mach, gimbal and configuration incompatibility of the four run sets.

The following tolerances were put on the data sets to check compatibility.

VARIABLE	TOLERANCE
MACH	.03
α	.25
β	.25
β	Sign
Gimbal	$\neq 0$
CONFIGURATION NO. DO NOT AGREE	
RUN NUMBER/SEQUENCE OUT OF PLACE	
δ_{INB}	$\pm .25$
δ_{OUT}	$\pm .25$

The SORT program proved very useful in identifying errors in the post test run schedule and differences between the power-on and power-off model attitude.

POWER DELTA PROGRAM

The Power Delta program was used to evaluate the change in the pressure data due to power. The program lists all data from the power on run and all data from the power off run and then subtracts the two data sets and lists the power delta's. This allows a rapid survey of the power delta's for abnormal numbers and a reference to the power on run and power off run to determine the error source.

SIGMA V PUNCH

The Sigma V Punch program was used in conjunction with the Power Delta program to sort the forebody power delta data into various elements and components and punch cards of the power delta in a format compatible with the "Wind Tunnel Pressure Data Analysis Program - WTPDA". WTPDA is an interactive graphic pressure data integration computer program which operates on the Sigma V Graphics System.

WIND TUNNEL PRESSURE DATA ANALYSIS (WTPDA)

WTPDA is an interactive computer graphics program which allows an engineer to apply his judgement to the smoothing of wind tunnel pressure data in a real time environment. The purpose of the program is to produce airloads which are compatible with vehicle stability data and which reflect engineering judgement. WTPDA employs interactive computer techniques so that an engineer can develop balanced airloads in a timely manner.

WTPDA can integrate pressure data on wings, vertical stabilizers, fins, cylinders, and arbitrary cross-section fuselages. Although WTPDA was developed specifically to handle the Space Shuttle launch vehicle, it is capable of handling almost any arbitrary cross-section body.

The WTPDA program was used to plot and smooth the power delta CP's on the forebody. Only limited integration of pressures were performed to check the main pressure integration computer program which is discussed below.

PLUME INDUCED PRESSURE INTEGRATION

The Plume Integration computer program was the main tool used to analyze the IA119 and IA135 pressure data. This computer program was developed

specifically to analyze the IA119 pressure data and was used to integrate the pressure data to obtain base and forebody plume induced aerodynamic loads and moments. The computer program was developed to analyze four run sequences of positive and negative β sets. This operation is required since portions of the model have pressure data on only one side. Thus, to analyze the effects of sideslip required the evaluation of + and - β runs. Both power-on and power-off data sets are required since a portion of the plume induced data uses power on pressure coefficients while other portions require only the change in pressure coefficient due to power.

The analysis of the plume induced aerodynamic characteristics was performed using different pressure data over different portions of the vehicle. This type of analysis was required because of the unique configuration of the Space Shuttle and the model configurations used to obtain the forebody aerodynamic characteristics. The two types of pressure data used for analysis are: 1) The power on C_p 's for nominal SSME and SRB model power settings; and 2) The power delta C_p 's where $\Delta C_{p_{Power}} = C_{p_{Power\ on}} - C_{p_{Power\ off}}$.

The power on C_p 's were used to evaluate the power-on base forces and moments. The power delta C_p 's were used to evaluate the change-in forebody aerodynamic characteristics. The location on the Space Shuttle vehicle where the different types of pressure data were used is shown in Figure 6-1. The results of integration of the base pressure and the forebody power delta pressures have been listed in a special format which is discussed in Section VII.

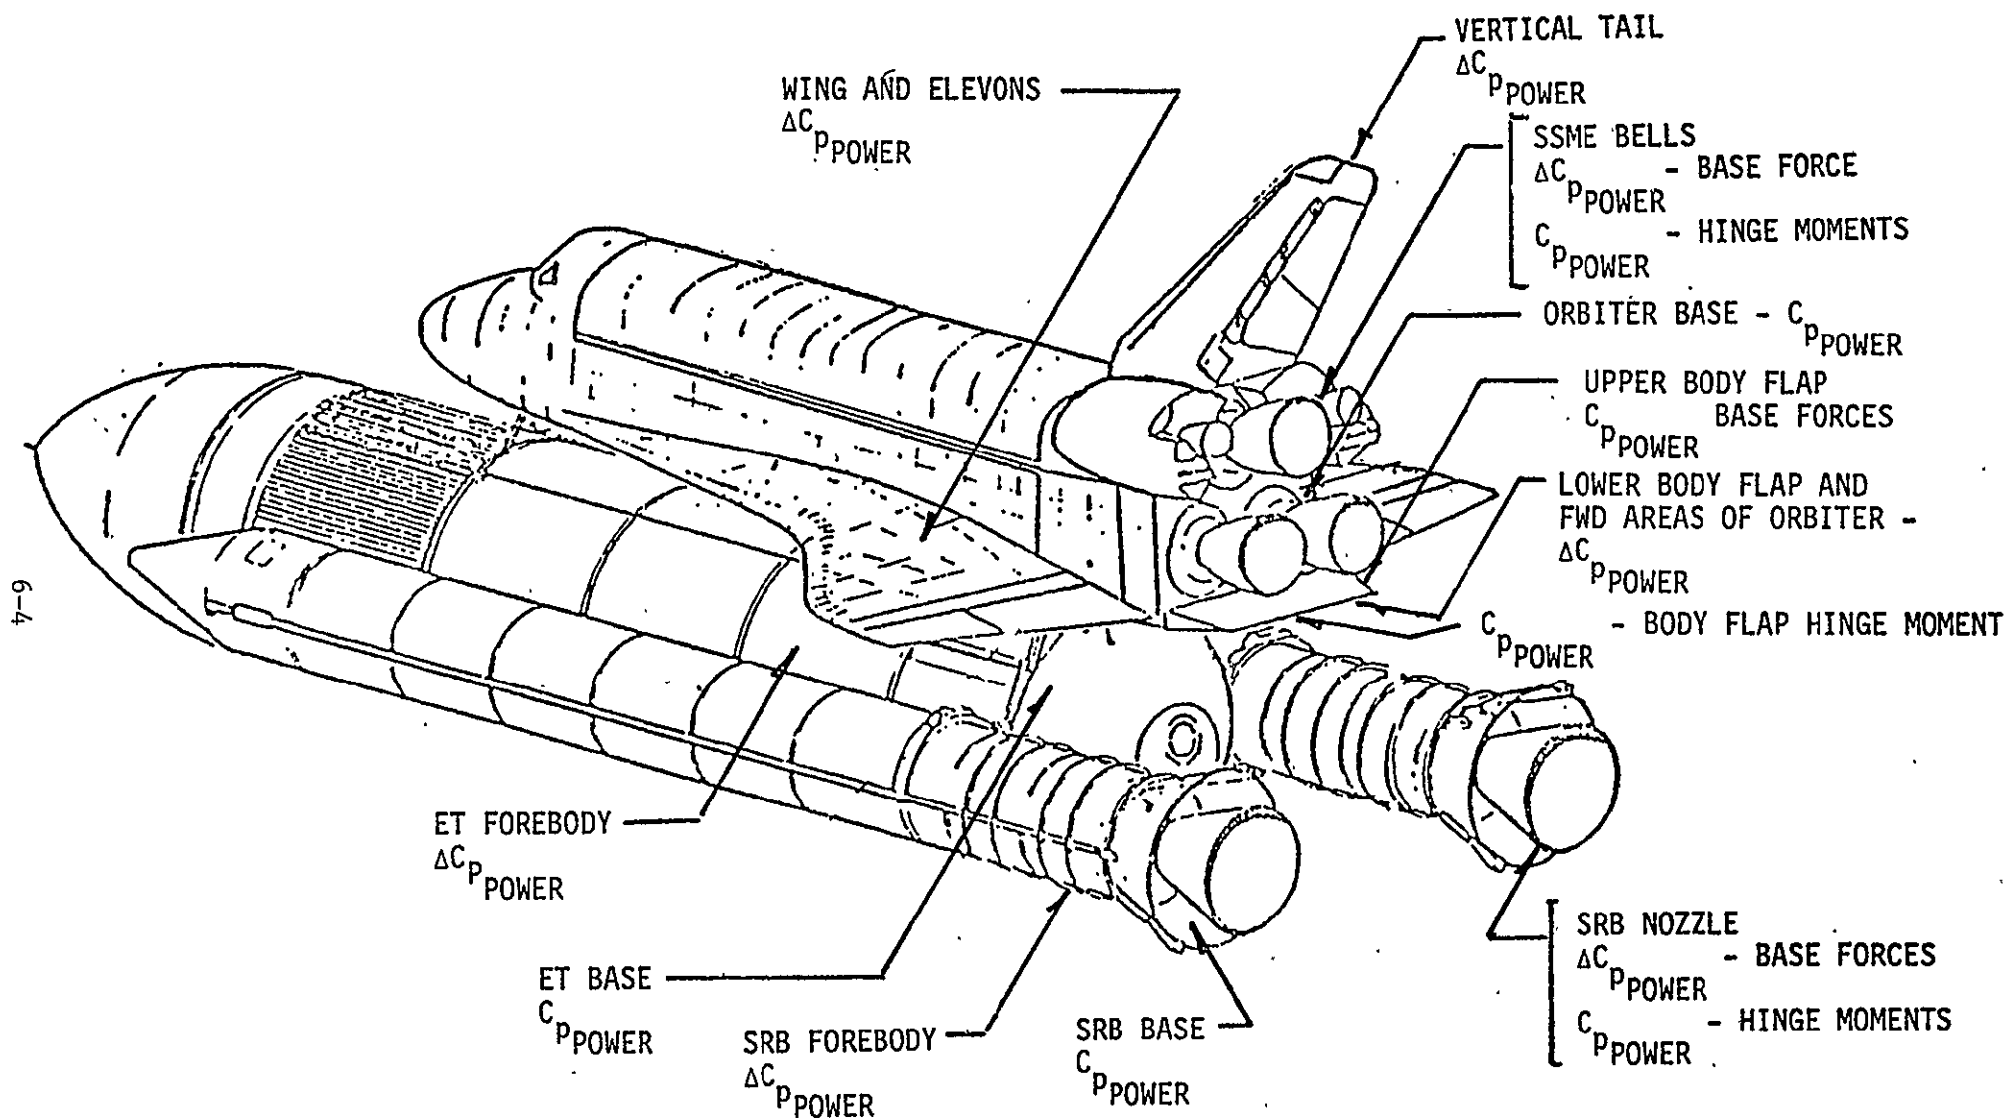

Figure 6-1. PLUME FLOW FIELD AREAS

Section VII TEST RESULTS

The results of the integration of the base pressure and forebody power delta's are presented in table form in the Appendix of references 1 and 2. The output of the Plume Integration computer program contains all the results of the pressure integration including base coefficients, forces and moments and forebody coefficient data from pressure integration along with the gage data.

An example of the printout of a data set from test IA119 is presented below. The data are arranged in 9 sections. Section 1 presents the run numbers, Mach number, vehicle configuration, and attitude. Section 2 presents the nozzle gas dynamic properties. Section 3 presents the nozzle gas dynamic similarity parameter. Section 4 presents the results of the pressure integration over the base elements and components. Section 5 presents the average base pressure coefficient for each element. Section 6 presents the nozzle average base pressure coefficients. Section 7 presents the nozzle hinge moment data. Section 8 presents the forebody data from the gages. Section 9 presents the forebody data from pressure integration.

BASE COEFFICIENTS			

Printouts of each run sequence set is presented in the Appendix of reference 1. The data sets are grouped for a constant Mach number. The first data set within a Mach group is the power-off runs. The second group contains the variable power runs. The third group are the various elevon deflections. The fourth group contains the various gimbal angle runs and the fifth group is a 90° roll run sets.

An example of the printout of a data set from test IA138 is presented below. The data are arranged in 9 sections. Section 1 presents the run numbers, Mach number, vehicle configuration and attitude. Section 2 presents the nozzle gas dynamic properties. Section 3 presents the plume gas dynamic similarity parameters. Section 4 presents the values of parameters used to determine the similarity parameters. Section 5 presents the results of the pressure integration over the base of the elements and components. Section 6 presents the average base pressure coefficient for each element. Section 7 presents the nozzle average base pressure coefficients. Section 8 presents the forebody data from the gages. Section 9 presents the forebody data from pressure integration.

Printouts of each run sequence set is presented in the appendix of reference 2. The data sets are grouped for a constant Mach number. The first data set within a Mach group is the power-off runs. The second group contains the variable power runs and the third group contains the various elevon deflections.

The base and forebody plume induced data tabulated on the printout sheets were analyzed and developed into math models. The math model is a description of the nominal aerodynamic data and a tolerance model. The math model of the base plume induced aerodynamic characteristics is presented in Section VIII. The math model of the forebody plume induced aerodynamic characteristics is presented in Section IX.

Section VIII

BASE MATH MODEL

A math model of the base plume induced aerodynamic characteristics was developed which can be used in conjunction with the forebody aerodynamic characteristics to evaluate the aerodynamic characteristics of the total space shuttle launch vehicle and each element. Three types of base aerodynamic characteristics were developed. These include 1. SSLV and element base aerodynamic coefficients for Mach numbers from 0.6 to 2.5, 2. SSLV base forces and moments versus altitude up to 160,000 ft. and 3. SSLV and element base coefficient tolerances for Mach numbers from 0.6 to 2.5. The math model consists of a description of the base aerodynamic coefficients at a given Mach number and elevon deflection for various α , β values. Gradients are provided giving the change in the aerodynamic characteristics with the two primary variables that influence the base flow (inboard elevon deflection and SSME power level).

The base aerodynamic math model is limited to the base axial force, normal force and pitching moment. Lateral-directional forces and moments exist on some base components, but no consistent trend could be identified and thus they are included in the base tolerance model. Base coefficients and tolerances for each element are provided for Mach numbers from 0.6 to 2.5. The base aerodynamic coefficient math model is described by the following equation,

$$C_{x_i} = [C_{x_i}]_{\alpha, \beta} + [\partial C_{x_i} / \partial \delta_{EI}] \times \Delta \delta_{EI} + [\partial C_{x_i} / \partial \% \text{ SSME POWER}] \times (\Delta \% \text{ SSME POWER})$$

where $[C_{x_i}]_{\alpha, \beta}$ is a 4x7 matrix for $\alpha = +4, 0, -4, -8$
 $\beta = -6, -4, -2, 0, 2, 4, 6$
 elevon deflection corresponds to close schedule 6
 $i = \text{SSLV, ORBITER, ET, LEFT SRB, RIGHT SRB}$

$\partial C_{x_i} / \partial \delta_{EI}$ Gradient for inboard elevon deflection -
 function of Mach number only
 $i = \text{SSLV, ORBITER, ET}$

$\partial C_{x_i} / \partial \text{SSME POWER}$ Gradient for percent change in SSME power level - function of Mach number only
 $i = \text{SSLV, ORBITER}$

$\Delta \delta_{EI}$ - Change in inboard elevon deflection from math model value to inboard elevon deflection of interest.

$\Delta \text{SSME POWER LEVEL}$ - Change in percent SSME power level from math model value to SSME power level of interest

Typical values of the coefficient $[C_{x_i}]_{\alpha, \beta}$ are presented in Tables 8-1, 8-2, and

8-3 for each element and the total SSLV vehicle. Typical values of the coefficient gradients are presented in Table 8-4.

Base forces and moments have been determined versus altitude using the base coefficient math model. The base force math model is for the total vehicle and uses the following model,

$$\left. \begin{matrix} F \\ M \end{matrix} \right|_{ALT} = \left. \begin{matrix} F \\ M \end{matrix} \right|_{\alpha=0} + \left[\frac{\partial F}{\partial \alpha} \right] \times \alpha + \left[\frac{\partial F_X}{\partial \delta_{EI}} \right] \Delta \delta_{EI} + \frac{\partial F}{\partial \% \text{ SSME POWER}} \times (\Delta \% \text{ SSME POWER})$$

where:

$\left. \begin{matrix} F \\ M \end{matrix} \right|_{\alpha=0}$ SSLV base force or moment - function of altitude only

$[\partial F / \partial \alpha]$ Gradient for angle of attack - function of only altitude

$[\partial F / \partial \delta_{EI}]$ Gradient for inboard elevon deflection - function of altitude only

$[\partial F / \partial \% \text{ SSME POWER}]$ Gradient for percent change in SSME power level

α angle of attack

$\Delta \delta_{EI}$ Change in inboard elevon deflection from math model value to inboard elevon deflection of interest

$\Delta\%$ SSME POWER level	Change in percent SSME power level from math model value to SSME power level of interest.
-----------------------------	---

Typical values of the base axial force, normal force and pitching moment are presented in Tables 8-5, 8-6, and 8-7. Typical values of the base force partials are presented in Table 8-8.

BASE COEFFICIENT TOLERANCES

Examples of the base coefficient tolerances are presented in Tables 8-9 and 8-10. The coefficient tolerances cover all attitudes and configurations from the base coefficients presented in the math model to flight data and are to a $+3\sigma$ level. The moment tolerances are considered to be only due to force tolerances. The moment tolerance due to the aerodynamic center location uncertainty being a smaller order of magnitude. Examples of the base moment coefficient increment equations are presented in Table 8-10.

The base tolerances include contributions due to 1. test instrumentation uncertainty, 2. simulation parameter uncertainty, 3. Reynolds number characteristics, 4. Model-tunnel testing uncertainties, 5. Pressure integration uncertainties and 6. Math model uncertainties. Each tolerance contribution is assumed independent and therefore the contributions are combined using the RSS technique. The tolerances thus cover the uncertainty from the math model to flight data and are to a $+3\sigma$ level with a Gaussian distribution.

The model instrumentation contribution included the accuracy of the Scanivalve^R calculations. The general accuracy is estimated to be $C_p = \pm 0.013$ for values of C_p in the range of ± 5 . The general uncertainty of the measured pressure coefficients was assumed to be 3%.

The simulation parameter uncertainty was assumed to be due to an uncertainty in the exponent. The estimated uncertainty in the exponent is shown in Figure 5-2. The exponent uncertainty was converted to an error in simulation that generally represented a 10 percent uncertainty in base force coefficients. The Reynolds number-scale uncertainty was obtained using past flight test to wind-tunnel test results. This factor is a judgement factor and includes the differences between the Saturn V and Titan 3C flight and wind tunnel data,

reduced to account for the plume technology program learning curve. This factor also includes a hot flow simulation uncertainty factor. The Reynolds number-scale uncertainty was generally 10% of the nominal base coefficient.

Model configuration uncertainties includes the effect of the support stings that will influence the flow field at angles of sideslip along with uncertainties due to other model configuration inaccuracies that potentially influence the local flow fields. Uncertainties due to model configuration similitude were approximately 7% of the nominal force coefficients.

Integration uncertainties included the potential error involved in the integration technique and represent approximately 3 percent of the nominal force coefficients.

The math model uncertainty included the errors of independent variables in the math model of the base forces and moments. Independent variables not included in the math model of the base forces and moments include nozzle gimbal angle and outboard elevon position.

The technique that was used to develop the SSLV base tolerances was to correlate the SRB and ET base tolerances and RSS those to the orbiter base coefficient tolerance. This procedure was used for the base axial force and normal force coefficients. The SSLV base side force coefficient was obtained by using the RSS technique for each element.

The forebody plume induced aerodynamic characteristics were developed in conjunction with the base plume induced aerodynamic characteristics to allow a complete description of the plume induced characteristics of the Space Shuttle Launch Vehicle. The forebody plume induced aerodynamic characteristics are presented in Section IX.

Table 8-10

BASE MOMENT INCREMENTS

The general equations for the element moment increments are

$$\Delta C_M = \Delta C_N \left(\frac{X_N}{L} \right) + \Delta C_A \left(\frac{Z_A}{L} \right)$$

$$\Delta C_{YN} = \Delta C_Y \left(\frac{X_{YN}}{L} \right)$$

$$\Delta C_{\ell} = \Delta C_Y \left(\frac{Z_L}{L} \right) + \Delta C_N \left(\frac{Y_L}{L} \right)$$

The SSLV moment increment is determined by the following equations

$$\Delta C_{M_{SSLV}} = \sqrt{(\Delta C_{M_O})^2 + (\Delta C_{M_{ET}} + \Delta C_{M_{RSRB}} + \Delta C_{M_{LSRB}})^2}$$

$$\Delta C_{Y_{N_{SSLV}}} = \sqrt{(\Delta C_{Y_{N_O}})^2 + (\Delta C_{Y_{N_{ET}}})^2 + (\Delta C_{Y_{N_{RSRB}}})^2 + (\Delta C_{Y_{N_{LSRB}}})^2}$$

Section IX

FOREBODY PLUME INDUCED MATH MODEL

The nominal forebody plume induced aerodynamic characteristics were small except on the Orbiter fuselage, inboard elevon and the vertical tail. Math models were thus developed for the SSLV, Orbiter, the inboard elevon hinge moment and the vertical tail. The SSLV and Orbiter normal force, pitching moment and inboard elevon hinge moment was formulated into the following math model.

$$\begin{aligned} C_N &= C_{N_{\alpha-\beta \text{ MATRIX}}} + \begin{bmatrix} \partial C_N / \partial \delta_{EI} \\ \alpha-\beta \\ \text{MATRIX} \\ > \\ < \end{bmatrix} \times \Delta \delta_{EI} + \begin{bmatrix} \partial C_N / \partial \delta_{EO} \\ > \\ < \end{bmatrix} \times \Delta \delta_{EO} \\ C_M &= \\ C_{H_{e_I}} &= \end{aligned}$$

where C_N is a 4x7 matrix for $\alpha = +4, 0, -4, -8$
 $\beta = -6, -4, -2, 0, 2, 4, 6$
elevon deflection corresponds to close schedule 6
 $\partial C_N / \partial \delta_{EI}$ is a 4x7 matrix for $\alpha = +4, 0, -4, -8$
 $\beta = -6, -4, -2, 0, 2, 4, 6$
 $>$ gradient for inboard elevon deflections $>$ nominal
 $<$ gradient for inboard elevon deflections $<$ nominal
 $\partial C_N / \partial \delta_{EO}$ is a 4.7 matrix for $\alpha = +4, 0, -4, -8$
 $\beta = -6, -4, -2, 0, 2, 4, 6$
 $>$ gradient for outboard elevon deflections $>$ nominal
 $<$ gradient for outboard elevon deflections $<$ nominal
 $\Delta \delta_{EI}$ - change in inboard elevon deflection from nominal value
to inboard elevon deflection of interest.
 $\Delta \delta_{EO}$ - change in outboard elevon deflection from nominal value
to outboard elevon deflection of interest.

Typical values of SSLV and Orbiter plume induced forebody normal force coefficients are presented in Table 9-1.

The orbiter normal force and pitching moment math models were derived from the results of the pressure integration of the power-delta pressure coefficients. The orbiter data used to derive the math model is presented in the tabulated data in the Appendix - Section 9 (Forebody Pressure Integration) of the printout sheet (see Section VII). The SSLV and Orbiter math models are identical since only the orbiter plume effects are included in the math model.

The hinge moment math model was derived from the left wing gage data, although the data is presented for the right wing. A comparison of the left wing gage data and the right wing pressure integration data was made to evaluate the best data to use and the gage data had the most consistent trend with changes in attitude and configuration. The left wing gage data used to develop the hinge moment math model is presented in the tabulated data in the appendix in Section 8 (GAGE DATA) of the printout sheet (see Section VII).

The vertical tail shear force, bending moment and torsion moment coefficient were formulated into the following math model

$$C_v = [C_{v_{\alpha-\beta}}]_{\text{Matrix}}$$

where

$$[C_{v_{\alpha-\beta}}]_{\text{Matrix}} \text{ is a } 4 \times 7 \text{ matrix for } \alpha = +4, 0, -4, -8 \\ \beta = -6, -4, -2, 0, 2, 4, 6$$

for elevon deflections noted on the table.

C_{YV} , vertical tail power delta shear force coefficient

C_{BV} , vertical tail power delta bending moment coefficient

C_{TV} , vertical tail power delta torsion moment coefficient

The vertical tail shear force math model includes only the α - β matrix at the nominal elevon deflection. No influence of elevon deflections are included. The vertical tail power induced shear force, bending moment, and torsion moment coefficients were developed into table format. A typical example is presented in Table 9-2.

The vertical tail math model was derived from the integration of the vertical tail pressure data presented in the tabulated data in the appendix in Section 9 (Forebody Pressure Integration) of the printout sheet (see Section VII).

FOREBODY COEFFICIENT TOLERANCES

Forebody tolerances have been developed for all forebody elements and components. As mentioned above, only the Orbiter, inboard elevon hinge moment and the vertical tail had measurable plume induced aerodynamic changes that could be effectively modeled. The other elements and components have zero nominal math model plume induced aerodynamic characteristics. Tolerances have been developed for all element and components, however, to account for all possible variations in plume induced aerodynamic characteristics. The forebody element and component force coefficient tolerances are presented as tabled values that are the $\pm 3\sigma$ variation of the nominal coefficient. The $\pm 3\sigma$ variation covers the potential variation of the coefficient from the math model results to expected flight data values.

Examples of the SSLV and element force coefficient tolerances are presented in Table 9-3. The moment increment equations are presented in Table 9-4. Examples of the component force coefficient tolerances and moment equations are presented in Tables 9-5 and 9-6. The moment tolerances require using equations that include the force coefficient tolerances along with the nominal aerodynamic center in conjunction with the nominal forebody power delta (when $\neq 0$) times the aerodynamic center tolerance.

The forebody tolerances include contributions due to 1. test instrumentation uncertainty, 2. simulation parameter uncertainty, 3. Reynolds number characteristics, 4. Model-tunnel testing uncertainties, 5. Pressure integration uncertainties and 6. Math model uncertainties. Each tolerance contribution is assumed independent and therefore the contributions are combined using the RSS technique. The tolerances thus cover the uncertainty from the math model to flight data and are to a $\pm 3\sigma$ level with a Gaussian distribution.

The forebody coefficients are determined using power delta's. Thus the instrumentation accuracy includes two independent measurements that are combined

by the RSS techniques. The instrumentation accuracy for a single measurement is estimated to be 3 percent. Thus two measurements would be 4.3 percent. The general uncertainty in the nominal forebody force coefficient due to instrumentation uncertainty was estimated at 50 percent of the calculated nominal forebody coefficient. The similarity parameter uncertainty was estimated to be 30 percent of the nominal, Reynolds number and scale effect was estimated to be 100 percent of the nominal, model uncertainties were estimated to be 30 percent of the nominal, integration uncertainties at 30 percent of the nominal and math model uncertainties were estimated at 20 percent of the nominal value. The net RSS tolerance value for the forebody coefficients are large compared to the nominal math model values. This is because the nominal math model force coefficients are small. If the math model is not used the tolerance would be approximately double the values presented and it was determined that forebody tolerances approach double the values would be excessive.

Portions of the forebody have zero nominal plume induced aerodynamic force coefficients in the math model although specific computed values have been determined and are listed in the tabulated data in the appendix (see Section VII). The tolerance analysis discussed above considered the nominal values calculated although the math model nominal force coefficients are zero.

Section X

CONCLUSIONS

The data from tests IA119 and IA138 resulted in an appreciable amount of good plume induced aerodynamic data. Problems with the data were very limited and the power off data compares very good with other tests.

The major independent variables that change the plume induced aerodynamic characteristics are angle of attack, angle of sideslip, inboard elevon deflection and SRB and SSME power level. Plume induced aerodynamic characteristics and their tolerances for the base and forebody have been developed into math models compatible with the forebody math models.

A math model of the plume induced aerodynamic coefficients for the base was developed for the Mach number range from 0.6 to 2.5. Data tables of these coefficients have been provided in G.E. mass format for computer simulation. A math model of the forces and moments for the base was also developed covering the portion of ascent flight up to 160,000 ft. The data tables for the base force math model was also provided in G.E. mass format. A math model of the forebody plume induced aerodynamic coefficients was also developed and the data tables provided in G.E. mass format. The tolerances for the plume induced aerodynamic coefficients and the tolerance math models for the base and forebody were developed and data tables provided in G.E. mass format.

The plume induced aerodynamic characteristics of the orbiter base are the result of a complicated integration of pressure coefficients and power delta pressure coefficients. These aerodynamic characteristics were developed such that when combined with the forebody data they produce the proper total vehicle aerodynamic characteristics.

The ET base plume induced axial force is larger than previous analyses have predicted, however, it is felt that the present results are consistent and representative of the ET base pressure environment.

The plume induced near field (base environment) and far field (orbiter forebody wing and hinge moment data) had good consistent trends when plotted versus the plume similarity parameter. The consistency of the data for both the near field and far field added confidence in the similarity parameter used.

Section XI

RECOMMENDATIONS

A computer program was developed to integrate the pressure data for all elements and components and tabulate the results and the results of the gage data. The tabulated results and plotted power variation data represent approximately 2000 computer printout pages. Time did not permit an extensive analysis of all the data. It is recommended that additional analyses be conducted of the vertical tail data, wing data, inboard hinge moment data and orbiter fuselage data.

It is also recommended that the IA119 and IA138 test results be reevaluated using the new similarity parameters.
